Constraint Satisfaction Problems

Sets of variables and constraint tensors
E.g. Satisfiability of a knowledge base is a CSP

Contraction criterion

A CSP is satisfiable if and only if its contraction does not vanish, that is

$$\langle \{ \tau^{\mathsf{e}} [X_{\mathsf{e}}] \, : \, \mathsf{e} \in \mathcal{E} \} \rangle_{[\varnothing]} \neq 0 \, .$$

While global contraction is a generic solver, it cannot be an efficient one.

Outline

- Sudoku
- Generalized unit propagation
- Graph Coloring
- Backtracking search
- Generic inference algorithms

Example: Sudoku

Consider grids of $n^2 \times n^2$ cells assigned by numbers in $[n^2]$, where usually $n = 3$ but for visualization purposes we will take $n = 2$.

Constraints:

- Each cell contains exactly one digit
- Each digit appears exactly once in each row, column and square

Example of a $2^2 \times 2^2$ Sudoku with initial clues and unique solution:

0			
	1		
		3	
	2		

$=$

0	3	2	1
2	1	0	3
1	0	3	2
3	2	1	0

Representation of Sudoku

We enumerate each cell by tuples $r_0 r_1 c_0 c_1 \in [n]^4$, where (r_0, r_1) select the $r_0 \cdot n + r_1$th row and $(c_0 c_1)$ the $c_0 \cdot n + c_1$th column:

$$\begin{array}{cccc} 0000 & 0001 & 0010 & 0011 \\ 0100 & 0101 & 0110 & 0111 \\ 1000 & 1001 & 1010 & 1011 \\ 1100 & 1101 & 1110 & 1111 \end{array}$$

For each possible assignment i to each cell $r_0 r_1 c_0 c_1$ we define a hidden variable $X_{r_0 r_1 c_0 c_1 i}$, which is 1 if the cell $r_0 r_1 c_0 c_1$ is assigned by i and 0 else.

$$\{X_{r_0 r_1 c_0 c_1 i} \,:\, r_0 r_1 c_0 c_1 \in [n],\, i \in [n^2]\}$$

Sudoku constraint tensors

Sudoku constraints enforce "exactly-one" condition by tensors $\tau\left[X_{\mathcal{U}}\right]$ with indices

$$\tau\left[X_{\mathcal{U}} = x_{\mathcal{U}}\right] = \begin{cases} 1 & \text{if} \quad \sum_{u \in \mathcal{U}} x_u = 1 \\ 0 & \text{else} \end{cases}$$

We choose $\mathcal{U}$ differently for each constraint:

- **Position constraints:** $\mathcal{U} = \{(r_0 r_1 c_0 c_1 i) \,:\, i \in [n^2]\}$ for each cell $r_0 r_1 c_0 c_1$
- **Row constraints:** $\mathcal{U} = \{(r_0 r_1 c_0 c_1 i) \,:\, c_0, c_1 \in [n]\}$ for each row $r_0 r_1$ and each digit i
- **Column constraints:** $\mathcal{U} = \{(r_0 r_1 c_0 c_1 i) \,:\, r_0, r_1 \in [n]\}$ for each column $c_0 c_1$ and each digit i
- **Square constraints:** $\mathcal{U} = \{(r_0 r_1 c_0 c_1 i) \,:\, r_1, c_1 \in [n]\}$ for each square $r_0 c_0$ and each digit i

Decomposition of Sudoku constraints

The constraints are decomposed using a decomposition variable $I \in [n^2]$ corresponding to the nonvanishing digit. This is enforce for each $i \in [n^2]$ by constraint matrices

$$\tau^i [X_i, I] = \epsilon_1 [X] \otimes \epsilon_i [I] + \epsilon_0 [X] \otimes (\mathbb{I} [I] - \epsilon_i [I]) \ .$$

For example:

$$\tau^2 [X, I] = \begin{pmatrix} 1 & 1 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix} [X, I]$$

In total we have a decomposition (in the so-called CP-format):

Outline

- Sudoku
- Generalized unit propagation
- Graph Coloring
- Backtracking search
- Generic inference algorithms

Disentangling the constraint network

Idea: When a CSP has a unique solution $x_{\mathcal{V}}$, then the contracted tensor is elementary:

$$\langle \{\tau^{e}\,[X_e] \,:\, e \in \mathcal{E}\} \rangle_{[X_{\mathcal{V}}]} = \bigotimes_{v \in \mathcal{V}} \epsilon_{x_v}\,[X_v]$$

Aim: Perform manipulation operations to disentangle the constraints.

1.Step:
Contract vector on constraint

2.Step:
Try to split into tensor product

Disentangling properties of Sudoku matrices

Contraction along I:

Contraction along X:

These disentangling matrix-vector contractions are exploited to solve (simple) Sudoku puzzles.

Disentangling a known position in Sudoku

Example: When 0 at position 0000, then no further digit can be assigned to that position.

We disentangle each atomic variable corresponding with a known position.

Disentangling a known position in Sudoku

Example: When 0 at position 0000, then no further digit can be assigned to that position.

We disentangle each atomic variable corresponding with a known position.

Disentangling a known position in Sudoku

Example: When 0 at position 0000, then no further digit can be assigned to that position.

We disentangle each atomic variable corresponding with a known position.

Generalized unit propagation

Generalized unit propagation: Do until convergence

- Contract a vector to each neighboring tensor
- Try to split the resulting tensor into a vector and a tensor
- If success and the remaining tensor is a vector: Repeat for the remaining vector

Comparison with unit propagation so far:

- Works with arbitrary constraints (shape, values), while so far on unit clauses
- Performs sub-contraction and tries to split the resulting tensor

Generalized unit propagation algorithm

Require: Constraint network $\tau^{\mathcal{G}}$

Ensure: Equivalent constraint network $\tau^{\mathcal{G}}$, with potentially less connectivity in $\mathcal{G}$

Initialize a queue Q of unary edges in $\mathcal{G}$
while Q not empty **do**
  $\{v\} = Q.pop()$
  for $e \in \mathcal{E} \ : \ v \in e$ **do**
    $\tau^{e}\left[X_e\right] \leftarrow \left\langle \tau^{e}\left[X_e\right], \tau^{\{v\}}\left[X_v\right] \right\rangle_{[X_e]}$
    Try to split $\tau^{e}\left[X_e\right]$ into a vector v and a tensor $e \backslash \{v\}$
    if Split successful and $|e \backslash \{v\}| = 1$ **then**
      $Q.push(e \backslash \{v\})$
    end if
  end for
end while
return $\tau^{\mathcal{G}}$

Matrix-vector example

Find the 2 in the first row:

0	3		1

Matrix-vector example

Find the 2 in the first row:

0	3	2	1

Matrix-vector example

Find the 2 in the first row:

0	3		1

With these matrix-vector contraction schemes, the example Sudoku can be solved:

0			
	1		
		3	
	2		

$=$

0	3	2	1
2	1	0	3
1	0	3	2
3	2	1	0

Generalized unit propagation

Same behaviour as classical Sudoku solvers:

- Dancing Links [Knuth: Art of Computer Programming, Vol. 4b]
- AC-3 [Mackworth: Consistency in Networks of Relations]

But: Often convergence without solution. On the Nicoli100 benchmark: 49% solved by generalized unit propagation.

Limitations

Example: Which cells cannot get a 2 assigned?

Limitations

Example: Which cells cannot get a 2 assigned?

Limitations

Example: Which cells cannot get a 2 assigned?

We need a contraction of four constraint matrices, to continue!

Limitations

Example: Which cells cannot get a 2 assigned?

Limitations

Example: Which cells cannot get a 2 assigned?

Result: Two cells can be excluded for 2.

Outline

- Sudoku
- Generalized unit propagation
- Graph Coloring
- Backtracking search
- Generic inference algorithms

Example: Graph Coloring

Graph Coloring Problem

Given a graph $\mathcal{G} = (\mathcal{V}, \mathcal{E})$ and m colors, find a coloring of the nodes, such that adjacent nodes have different colors.

Example: Paint the states of australia

- How many colors are required?
- How many possible colorings can be done?

Representation of Graph Coloring

We model the problem:

- Enumerate the colors by the state set $[m] = \{0, \ldots, m-1\}$
- For each node $v \in \mathcal{V}$ we define a variable X_v

To each edge $e = \{v_0, v_1\}$ the "different" constraint matrix

$$\tau^{\mathrm{diff},\{v_0,v_1\}}\left[X_{v_0}, X_{v_1}\right] = \mathbb{I}\left[X_{v_0}, X_{v_1}\right] - \delta\left[X_{v_0}, X_{v_1}\right] .$$

with off-diagonal support enforces different color constraint.

$$\tau^{\{v_0,v_1\}}\left[X_{v_0}, X_{v_1}\right] = \begin{pmatrix} 0 & 1 & \cdots & 1 \\ 1 & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & 1 \\ 1 & \cdots & 1 & 0 \end{pmatrix} \left[X_{v_0}, X_{v_1}\right]$$

Example: Painting states of australia

Let us paint the states of australia with 3 colors:

- 7 color variables $X_.$ of leg dimension $m = 3$
- 9 edges between neighbored states v_0 and v_1, which are decorated by the 3x3 constraint matrix

$$\tau^{\{v_0,v_1\}}[X_{v_0}, X_{v_1}] = \begin{pmatrix} 0 & 1 & 1 \\ 1 & 0 & 1 \\ 1 & 1 & 0 \end{pmatrix} [X_{v_0}, X_{v_1}]$$

Example: Cycle of three nodes

Is a cycle of three nodes colorable by two colors?

Cannot detect the unsatisfiability by contractions of two matrices.
In general: Cycles with odd numbers need three colors, of two need two colors.

Example: Cycle of three nodes

By three variables colorable: The contracted tensor has 6 non-vanishing entries, which correspond to the 6 possible colorings of the three nodes by three colors.

$$\begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix} \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix} \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

Disentangling properties of the "different" constraint

When contracting the "different" constraint with a vector, we get

$$\mathbb{I}_{\neq 0} \circ \left\langle V[X_{v_0}], \tau^{\{v_0,v_1\}}\left[X_{v_0}, X_{v_1}\right]\right\rangle_{[X_{v_1}]}$$
$$= \begin{cases} \mathbb{I}\left[X_{v_1}\right] - \epsilon_y\left[X_{v_1}\right] & \text{if } V[X_{v_0}] \text{ only at } y \text{ supported} \\ \mathbb{I}\left[X_{v_1}\right] & \text{else} \end{cases}.$$

The "different" constraint has weakest disentangling properties:

Disentangling only possible, when the vector is basis (i.e. the color of one node is known).

Consequence: Unit propagation helps only, when the color of one node v_0 is known:

But where to find the basis vectors necessary for disentangling the color constraints?

Outline

- Sudoku
- Generalized unit propagation
- Graph Coloring
- Backtracking search
- Generic inference algorithms

Idea of backtracking

Guess an assignment to disentangle a node. When running into an inconsistency, guess an alternative assignment.
We do this until a non-vanishing elementary constraint network is reached.
From this (possibly multiple) solutions can be constructed by local solutions.

Backtracking algorithm

Require: Constraint network $\tau^{\mathcal{G}}$
Ensure: Elementary constraint network

Choose a node v in a non-unitary edge e
for $x_v \in [m_v]$ **do**
  $\tilde{\tau^{\mathcal{G}}} \leftarrow \tau^{\mathcal{G}} \cup \{\epsilon_{x_v}[X_v]\}$
  $\tilde{\tau^{\mathcal{G}}} \leftarrow \mathrm{Simplify}(\tilde{\tau^{\mathcal{G}}})$ (differing realization)
  if $\tilde{\tau^{\mathcal{G}}}$ vanishing **then**
    return *False*
  end if
  $\tilde{\tau^{\mathcal{G}}} \leftarrow \mathrm{Backtrack}(\tau^{\mathcal{G}} \cup \{\epsilon_{x_v}[X_v]\})$
  if $\tau^{\mathcal{G}}$ not *False* **then**
    return $\tau^{\mathcal{G}}$
  end if
end for
return *False*

Combination with constraint simplification

Do generic unit propagation in an inner loop to simplify constraints before guessing.

Example: Painting australias states

Take three colors: red, blue, green

-

Example: Painting australias states

Take three colors: red, blue, green

- Guess X_{WA} to be red.
- GUP finds consequences for X_{NT} and X_{SA}: red or green
- Guess X_{NT} to be green.
- GUP dermines X_{SA} to be blue.
- GUP determines also X_Q, X_{NSW}, X_V.
-

Example: Painting australias states

Take three colors: red, blue, green

- Guess X_{WA} to be red.
- GUP finds consequences for X_{NT} and X_{SA}: red or green
- Guess X_{NT} to be green.
- GUP dermines X_{SA} to be blue.
- GUP determines also X_Q, X_{NSW}, X_V.
- The variable X_T is disconnected and can be chosen arbitrarly.

Outline

- Sudoku
- Generalized unit propagation
- Graph Coloring
- Backtracking search
- Generic inference algorithms

So far

Generalized unit propagation choices subsets $\tilde{\mathcal{G}}$ as:

- Two constraint tensors
- One constraint tensor is of order 1 (i.e. a vector)

More complex reasoning steps: Contraction of multiple constraint tensors with larger order, keeping only a subset open.

Recall: Support tensors

Support tensor to a tensor $\tau\left[X_{[d]}\right]$: $\mathbb{I}_{\neq 0}\left(\tau\left[X_{[d]}\right]\right)$ with coordinates

$$\mathbb{I}_{\neq 0}\left(\tau\left[X_{[d]} = x_{[d]}\right]\right) = \begin{cases} 1 & \text{if} \quad \tau\left[X_0 = x_0, \ldots, X_{d-1} = x_{d-1}\right] \neq 0 \\ 0 & \text{else} \end{cases}$$

Invariance under adding support tensor to sub-contractions

Any support tensor of a sub-contraction can be added to a tensor network: When $\tilde{\mathcal{G}}$ a sub-hypergraph of $\mathcal{G}$, then

$$\left\langle \tau^{\mathcal{G}}\left[X_{[d]}\right]\right\rangle_{[X_{\mathcal{V}}]} = \left\langle \tau^{\mathcal{G}}\left[X_{[d]}\right], \mathbb{I}_{\neq 0}\left(\left\langle \tau^{\tilde{\mathcal{G}}}\left[X_{\mathcal{V}}\right]\right\rangle_{[X_{\mathcal{U}}]}\right)\right\rangle_{[X_{\mathcal{V}}]}$$

In propositional logics, this means:

$$\mathbb{I}_{\neq 0}\left(\left\langle \tau^{\mathcal{G}}\left[X_{[d]}\right]\right\rangle_{[X_{\mathcal{V}}]}\right) \models \mathbb{I}_{\neq 0}\left(\left\langle \tau^{\tilde{\mathcal{G}}}\left[X_{\mathcal{V}}\right]\right\rangle_{[X_{\mathcal{U}}]}\right)$$

Outlook

Sub-contractions model inference rules

- Logics: Modus ponens, resolutions
- CSPs: arc-consistency

Tradeoff in the sub-contraction size:

- Efficiency: Number of possible sub-contractions, computational demand to perform a sub-contraction
- Generality: Larger contractions can perform more complex reasoning steps
